Generative AI & Chatbot Development

Assignment #01

Submitted By:
Wajid Ali

Roll Number:
AIC-882016

Submitted To:
Professor Abu Huraira

Due Date:
22th October, 2026

Share how will you use Ai Agents to grow business

Proposed business idea: JobPilot AI

I propose JobPilot AI, a subscription service that helps job seekers organize their search and prepare tailored applications for jobs they select. A user stores their skills, projects, and experience once. For each chosen job, an AI agent checks the match, suggests truthful resume changes, drafts an application email, and records the application. The user reviews and approves each message before it is sent. This is a proposed business concept, not a claim that the service has already launched or achieved results.

1. What Is My Target Audience?

My main audience would be fresh graduates and junior information technology professionals who apply to many roles and find it difficult to tailor each application. The service could also support career switchers, remote and freelance applicants, and working professionals who have limited time to manage a job search.

Audience segment	Who they are	Problem the service could address
Fresh graduates and juniors in IT (main audience)	Ages 21–28, applying to 50–100+ jobs	They get few replies and don't know how to match keywords
Career switchers	Professionals moving into software, data or AI	They need help connecting previous work and projects to the requirements of a new field.
Remote and freelance applicants	People applying to international companies	They manage applications across time zones and need clear, professional messages.
Working professionals	People looking quietly for a better job	They have limited time to tailor resumes and remember follow-ups.

I would begin with students and junior applicants in information technology because the service can focus on a specific set of roles and skills. Their needs and willingness to use or pay for the service would need to be validated through interviews and feedback; I would not assume demand without that evidence.

Common job-search difficulties the proposed service could address include:

1. Tailoring a resume for each opening can take substantial time.
2. Applicant tracking systems may use role requirements and keywords to organize applications, so applicants can benefit from clearly presenting relevant experience. A tailored resume cannot guarantee that it will pass a screening system.
3. Applicants may lose track of submitted applications, replies, interviews, or follow-up dates.

2. Where Would I Find Their Data and Why?

The service would use two main categories of information: a profile supplied by the user and job information from listings the user selects or from sources that permit the intended access.

Data source	Information it may provide	Why it is useful
User-provided master profile	Skills, education, projects, certificates, experience, and achievements.	It gives the agent a source of verified facts to use when comparing jobs and drafting materials.
Jobs selected by the user	A job URL or pasted description, title, company, requirements, and application instructions.	It shows what the applicant wants to evaluate and tailor materials for.
Authorized job sources	Listings from official APIs, permitted feeds, partner datasets, or public pages whose terms allow the intended use.	They can widen the range of relevant opportunities while respecting source rules.
Job alert emails and RSS feeds	New openings matching selected roles or skills.	They can help the service surface new opportunities from sources that permit this use.
Application tracker	Company, role, date, match explanation, and user-selected status such as drafted, sent, interview, or closed.	It helps the user stay organized and review their own progress.
Public market and community feedback	Aggregated skill trends and user feedback from sources where collection and reuse are allowed.	It can guide future features and help users identify skills they may want to develop.

The service would ask for consent before using profile or resume information, collect only what it needs, secure stored data, and let users correct or remove their information. It would follow each source's terms and applicable privacy requirements. It would not sell personal profile data. Automatically collecting data from a website would happen only where that access is permitted; otherwise, users could provide a listing link or description themselves.

3. How Will the AI Agent Help?

An AI agent is software that can gather information, make a bounded decision, use connected tools, and report its result. The JobPilot AI agent would assist the applicant through four steps:

1. Collect. Load the user's saved profile and the job details the user selected, such as a URL or pasted description. Ask the user to provide or confirm any missing information, including a recruiter email address.
2. Analyze. Extract role requirements and compare them with the user's profile. Give a match score as a prioritization aid and explain which skills or experience support the score, which requirements appear missing, and what remains uncertain. A proposed starting rule could flag jobs at 60% or above for review and place lower-scoring jobs in a lower-priority list; this score would not determine eligibility or predict hiring.
3. Prepare. For a job the user chooses, suggest reordering relevant skills and projects, draft a role-specific summary, and write a polite application email. The agent must use only facts already supplied or confirmed by the user. It must not invent skills, experience, or achievements.
4. Report. Save the date, company, role, match explanation, missing skills, and status in an application tracker. The user can use the record to remember which applications are drafts, sent, skipped, or awaiting a response.

How the Workflow Could Map to n8n

Agent step	Possible n8n components	Result
Collect	Form, Google Sheets trigger, or manual input; HTTP Request only for an authorized source.	A user-selected job and profile details.
Analyze	AI node to extract requirements; Code node to compare explicit criteria and calculate a score.	A match explanation, score, and missing requirements.
Prepare	AI node to draft resume edits and email; Gmail draft or approval step.	Editable materials that use confirmed facts.
Report	Google Sheets or database node to update the tracker.	A dated record of the user-approved action.

Any email node should wait for the user's explicit approval for that particular application. The agent should not apply to every listing automatically.

Benefits for Customers and the Business

- Time saved: the service could reduce repetitive searching, formatting, and tracking work.
- More relevant applications: users can see how their stated skills relate to a job and decide where to focus.
- Clearer next steps: the agent can point out requirements the user may want to learn or demonstrate in future projects.
- Better organization: a tracker can keep deadlines and application statuses in one place.
- Truthful materials: the agent would reorganize and rewrite only facts that the user has provided or confirmed.

A possible business model is a free plan with up to five applications per month and a paid plan with higher or unlimited usage. Pricing and limits would need to be tested with users and balanced against the cost of model and data services.

Human Review and Responsible Use

The agent would prepare work and recommendations, while the user remains responsible for choosing jobs and approving applications. The user would check the job listing, match explanation, resume edits, recipient, and email content before sending. The service would use permitted data sources, respect their terms and rate limits, protect personal information, and avoid bypassing access controls. If a source does not permit automated access, the workflow would rely on a user-provided link or description and direct the user to the original listing.

How I Would Measure Success

I would test a small prototype with users and measure whether it solves a real problem before expanding it. Possible measures include:

- Applications drafted and sent per user, while keeping user approval in place.
- Time spent preparing an application compared with the user's previous process.
- Reply or interview rates, compared over time and described carefully because many factors affect hiring outcomes.
- Whether users find the recommendations accurate and understandable.
- Free-to-paid conversion and monthly cancellations if a paid version is tested.

Conclusion

JobPilot AI is my proposed way to use AI agents to help students and early-career applicants manage a demanding job search. It would use user-provided profile information and job data from sources that permit the intended access. The agent could compare requirements with a profile, explain potential matches, draft truthful application materials, and maintain a tracker. Keeping the user in control of each application would make the service more careful and trustworthy. If a small prototype proves useful through user feedback and measured time savings, the idea could grow into a sustainable subscription service.
